## Abstract

In the present investigation, biogenic silver nanoparticles were synthesized using aqueous extract of Mexican poppy plant *Argemone mexicana* (AM-Ag NPs); their involvement in striking cytotoxicity and genotoxicity potential was explored. The biosynthesis of nanoparticles was confirmed by ultraviolet-visible spectroscopy (UV-Vis) and characterized by scanning electron microscopy (SEM), transmission electron microscopy (TEM), Fourier transform-infrared spectrometry (FTIR) and X-ray diffraction (XRD). The mechanism of inhibition of cell proliferation by Ag NPs was illustrated using human cervical adenocarcinoma (HeLa), human breast adenocarcinoma (MCF-7) and human colon adenocarcinoma (HCT-15) cells. In selected cancer cells, molecular mechanism involved in induction of apoptosis in response to biogenic Ag NPs was demonstrated by DNA fragmentation assay, and alteration in expression of apoptotic genes including caspase-3 and p53 was analyzed by RT-PCR and western blotting. The overall results construed that biosynthesized AM-Ag NPs exhibited cytotoxicity effect against tested HeLa, MCF-7 and HCT-15 cell lines in a dose dependent manner where 20 µg/mL concentration of AM-Ag NPs killed more than 95% of HeLa and MCF-7 cells after 24 h exposure, whereas HCT-15 cells required 50 µg/mL AM-Ag NPs to inhibit 95% cell growth. AM-Ag NPs significantly induced cellular DNA damage in HeLa and MCF-7 cells when treated up to 20 µg/mL and HCT-15 cells exposed up to 50 µg/mL concentrations for 24 h. It is evident from our finding that the underlying mechanism of cell death in cancer cells exposed to AM-Ag NPs was intrinsic apoptosis pathway mediated by activation of caspase-3 and p53 genes.

## Introduction

Over the recent years, numerous studies have been carried out on biological synthesis of metal nanoparticles and their utilization in industrial and agriculture applications which are now building enormous interest in the healthcare sector too [1].

Amongst them silver and gold nanoparticles are widely studied for their synthesis using plant extracts and their comprehensive applications. Phytochemicals from different parts of plants such as leaves, stem, roots, shoots, flowers, bark and fruits have been utilized for synthesis of nanoparticles especially silver and gold nanoparticles [2-5]. Several reviews have been made

available of the synthesis and characterization of silver nanoparticles but with limited information on their mechanism of action [6, 7]. Nowadays, biosynthesized nanoparticles have emerged as novel therapeutic approach in healthcare system for the mechanistic management of both infectious as well as noninfectious diseases. Particularly, silver nanoparticles are widely noted for their antimicrobial properties against broad range of bacterial species [7, 8] and anticancer properties [9-13]. The cytotoxicity of silver nanoparticles is reported to be triggered by oxidative stress induced by free radicals such as reactive oxygen species (ROS) which inhibits cell proliferation through induction of programmed cell death [14-16]. But the clear molecular mechanism involved in arrest of cell proliferation remains unresolved dispute till date.

Currently employed chemotherapeutic approach dealing with cancer cells but facing severe obstacles such as multi drug resistance and severe aftereffects are considered as notable downsides in cancer management which results cancer as influential executioner all around the world. Subsequently, the discovery of new cancer targeting strategy with progressively influential and low harm to host immune system has become a basic objective in chemotherapeutics. Therefore, there is a developing interest in growing new and increasingly compelling classes of adjuvant therapeutic remedy for advanced cancer management with better biocompatibility and effectiveness. Use of biogenic nanoparticles is one of the rising and most promising therapeutic contrivances extensively studied in past few decades for their effectiveness against cancer cells. It has been reported earlier that silver nanoparticles can induce cell death through oxidative stress and p53 mediated apoptotic pathway in human carcinomas [17, 18]. Also, very recently, Bethu et al. proposed the anticancer activity of silver nanoparticles synthesized using *Rhynchosia suaveolens* was because of trigger in apoptosis signaling pathway in human ovarian, prostate and lung cancer cell lines [19]. Similarly, Kanipandian et al. reported induction of intrinsic apoptosis pathway in lung cancer cell lines in response to silver nanoparticles synthesized using *Gossypium hirsutum* [20].

In order to substantiate these findings, this study was intended to synthesize silver nanoparticles biogenically using fresh leaf extracts of *Argemone mexicana* L. and to explore possible mechanism involved in inhibition cell proliferation. *Argemone mexicana* is commonly known as Mexican poppy plant reported with multiple

medicinal benefits [21, 22]. Earlier bio-synthesized silver nanoparticles using *A. mexicana* were studied for their antimicrobial and antioxidant potential [23, 24]. However, possible mechanism involved in cytotoxicity and genotoxicity effects of either of silver or any other type of metal nanoparticles synthesized using *A. mexicana* plant extract remain unrevealed. Therefore, in the present study, we have attempted to evidence the molecular events involved in cytotoxicity and genotoxicity of *Argemone mexicana* silver nanoparticles (AM-Ag NPs) against various cancer cell lines including HeLa, MCF-7 and HCT-15. The cytotoxicity potential of AM-Ag NPs was explored by 3-(4,5-dimethylthiazol-2-yl) 2,5-diphenyltetrazolium bromide (MTT) colorimetric assay. The possible molecular mechanism of action for cell death or apoptotic features was addressed through DNA fragmentation assay; alterations in apoptotic genes at mRNA and protein level were determined by semi-quantitative reverse transcriptase-polymerase chain reaction (RT-PCR) and western blotting, respectively.

## Experimental

### Materials

HeLa, MCF-7 and HCT-15 cells were procured from National Centre for Cell Sciences, Pune. Minimum essential medium (MEM), RPMI1640, fetal bovine serum (FBS), trypsin-EDTA, and penicillin-streptomycin were purchased from Gibco. 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) was from Sigma.  $\text{AgNO}_3$ , Tris-HCl, ethylenediaminetetraacetate, Triton X-100, PMSF, dithiothreitol, and sodium dodecyl sulphate were from Sisco Research Laboratories. Caspase-3, p-53, and anti-actin, goat anti-rabbit IgG and rabbit anti-mouse IgG antibodies were from Abcam. Other equipment included WesternBright™ ECL detection system (Advansta), Verso cDNA synthesis kit (Thermo Scientific), Taq DNA polymerase, dNTPs, and low EEO agarose from (GeNei)

### Biosynthesis and purification of silver nanoparticles

The silver nanoparticles were synthesized by adding 10 mL of aqueous plant extract of *A. mexicana* to 90 mL of 1 milli molar (mM) silver nitrate ( $\text{AgNO}_3$ ) solution. The preparation was then incubated at 80 °C in dark with continuous shaking and monitored for synthesis of nanoparticles with change in colour of reaction mixture. After formation of AM-Ag NPs,

the mixture was centrifuged at 15,000 rpm for 10 min and washed several times with sterile deionized distilled water (ddw) to remove unwanted traces of contaminants followed by redispersion of the pellet in sterile ddw for further characterizations.

### Visual observation

The reduction of silver nitrate using aqueous plant extract was monitored for time periods of 0.5, 1, 2, 3, 4 and 5 h, and the appearance of dark brown color indicated the formation of silver nanoparticles.

### UV-visible spectroscopy analysis

Preliminary characterization of biosynthesized Ag NPs was carried out using UV-visible spectroscopy. The bio-reduction of pure silver ions was monitored by scanning ultraviolet-visible spectra of the reaction mixture at a wavelength of 300-800 nm by sampling the aliquots withdrawn from reaction mixture at different time intervals. The measurements were recorded on UV-visible dual beam spectrophotometer, UV-1800 Shimadzu.

### Characterization of biogenic AM-Ag NPs

Characterization of biosynthesized AM-Ag NPs was carried out by SEM, TEM, XRD and FTIR at Sophisticated Analytical Instrument Facility at Sophisticated Test and Instrumentation Centre, Cochin University, Kerala.

### In vitro evaluation of cytotoxicity activity of AM-Ag NPs

#### Cell lines and cell culture

The HeLa and MCF-7 cells were maintained in T-25 flasks containing MEM media, whereas HCT-15 cells were maintained in RPMI1640 media along with 10% heat inactivated FBS and penicillin-streptomycin at 100 U/mL and 100 µg/mL respectively. Cells were maintained under an atmosphere of 5% CO<sub>2</sub>, 95% humidity and 37 °C temperature. The primary fibroblasts cells obtained from breast tissue were cultured in DMEM/F12 media supplemented with containing FBS (10%), Pen-strep100 (U/mL), EGF (10 ng/mL), insulin (5 µg/mL), pituitary extract (50 ng/mL), and hydrocortisone (0.5 µg/mL).

#### In vitro cell viability assay

To study the inhibitory effects of AM-Ag NPs, the cells were maintained in MEM, RPMI-1640 as well as DMEM/F12 medium supplemented with 10% FBS, penicillin-streptomycin at 100 U/mL/100 µg/mL in a

humidified atmosphere of 5% CO<sub>2</sub> at 37 °C. 10,000 cells in 200 µL of respective medium per well were seeded in a 96 well plate and incubated at 37 °C, 5% CO<sub>2</sub>. After 24 h incubation, confluent cells were exposed to different concentrations of 0.5, 1.0, 2.5, 5, 7.5, 10, 15, 20, 25 and 50 µg/mL of nanoparticles in culture medium without FBS and incubated for further 48 h at 37 °C, 5 % CO<sub>2</sub>. Thereafter, 10 µL/well of 5 mg/mL concentration of MTT was added to the cells and further incubated for another 4 h at 37 °C. After 4 h incubation, 200 µL of DMSO was added to each well to dissolve the formazan crystals. The absorbance of purple color developed was measured at 560 nm wavelength using UV-Visible 1800 Spectrophotometer to determine percentage inhibition of growth of treated as well as untreated cells.

### DNA fragmentation assay

In order to check apoptosis, DNA fragmentation assay was performed. In brief,  $1 \times 10^6$  cells (HeLa and MCF-7) in 6 well plates were treated with 2.5, 5, 10, 15 and 20 µg/mL, and HCT-15 cells treated with 5, 10, 20, 25 and 50 µg/mL concentrations of AM-Ag NPs along with untreated controls and incubated at 37 °C in 5% CO<sub>2</sub> for 24 h. Cells were lysed in 0.3 mL of cell lysis buffer containing 10 mM Tris-HCl, pH 7.5, 1 mM EDTA, 0.2% Triton X-100, and 0.5% SDS. The cell lysate was incubated with 0.5 mg/mL RNase A at 37 °C for 1 h. DNA in aqueous phase was precipitated by adding 1/10<sup>th</sup> volume of 5 M sodium chloride and equal volume of isopropanol at room temperature. After 1 h incubation, the suspension was centrifuged at 12,000 rpm for 30 min at 4 °C followed by DNA pellet wash by 70% ice cold ethanol and air-dried DNA pellet for 10 min at room temperature. The DNA was re-suspended in appropriate volume of T<sub>10</sub>E<sub>1</sub> buffer (pH 8.0). DNA was checked on 1.5% (w/v) low EEO agarose gel containing 1 µg/mL ethidium bromide. The DNA fragments were visualized by exposing the gels to UV transilluminator followed by photography in gel documentation system (BioRad Laboratories, USA).

### Semiquantitative RT-PCR analysis for apoptotic gene expression

The change in expression profile of caspase-3 and p53 genes was identified using RT-PCR analysis. In this study, total RNA was extracted from control and AM-Ag NP (IC<sub>50</sub> concentration) treated cells by the Trizol reagent. The cDNA was synthesized from equal amounts of RNA (5 µg) using cDNA synthesis kit in 20 µL reaction containing 1 µL verso enzyme

mix containing reverse transcriptase, 4  $\mu$ L 5  $\times$  cDNA synthesis buffer, 2  $\mu$ L of dNTPs (0.5 mM each), 1  $\mu$ L of RT enhancer, 1  $\mu$ L of mixture of random hexamers and anchored oligo dT (3 : 1). cDNA synthesis was performed by reverse transcription cycling programme at 42 °C for 30 min followed by inactivation at 95 °C for 2 min to remove contaminating DNA. Thereafter, semi-quantitative RT-PCR amplification was performed where 2  $\mu$ L of each cDNA was amplified in a 20  $\mu$ L PCR reaction mixture containing 1 unit Taq DNA polymerase, 2  $\mu$ L 10 $\times$  PCR buffer, 0.5  $\mu$ L of dNTP (200  $\mu$ M each) and 10 picomoles of respective primers (caspase-3 forward primer 5'-gtggcattgagacagacagtgg-3' caspase-3 reverse primer 5'-gccagaataataaccaggtgc-3' and p53 forward primer 5'-actaagcgagcactgcccaa-3' reverse primer 5'-atggcgggaggtagactgac-3'). The cycling conditions were comprised of an initial denaturation of 5 min at 94 °C followed by 30 cycles of amplification at 94 °C for 30 sec, 50 °C for 30 sec and 72 °C for 30 sec, and the final elongation step at 72 °C for 10 min. To control the PCR reaction components and the integrity of the RNA, 2  $\mu$ L of each cDNA sample was amplified separately for b-actin specific primers (forward primer 5'-tctggcaccacacctctacaatg-3' reverse primer 5'-agcacagcctggatagcaacg-3'). Electrophoretic separation of amplification products was performed with 2.5% agarose gel in TBE buffer. Relative density of ethidium bromide stained amplicons was determined using image analysis software Image Lab 3.0 software (BioRad, USA)

### Western blotting analysis

Western blotting was performed to detect the expression of apoptotic proteins such as caspase-3 and p53 in HeLa, MCF-7 and HCT-15 cells. 1  $\times$  10<sup>6</sup> cells grown in 6 well plates and treated with IC<sub>50</sub> concentration of AM-Ag NPs for 48 h, and were harvested with centrifugation at 12,000 rpm for 10 min at 24 h intervals. Cell pellet was immediately lysed in homogenizing buffer (50 mM Tris, 5 mM EDTA, 0.1% Triton X-100, 1 mM PMSF, 0.5 mM DTT, and protease inhibitor cocktail); cell lysates were centrifuged at 12,000 rpm at 4 °C. Defined amount of total protein (50  $\mu$ g/lane) was separated on 10% SDS-PAGE and then transferred onto a nitrocellulose membrane. Subsequently, membranes were blocked in TBST solution containing 5% casein for 1 h followed by probing with primary antibodies, rabbit anti-caspase-3, anti-actin and mouse anti-p53. After washing with TBST solution, the membranes were

incubated with secondary antibodies (horseradish peroxidase-conjugated goat anti-rabbit IgG and rabbit anti-mouse IgG). Immunoreactive bands were detected using enhanced chemiluminescence WesternBright™ ECL detection system.

### Statistical analysis

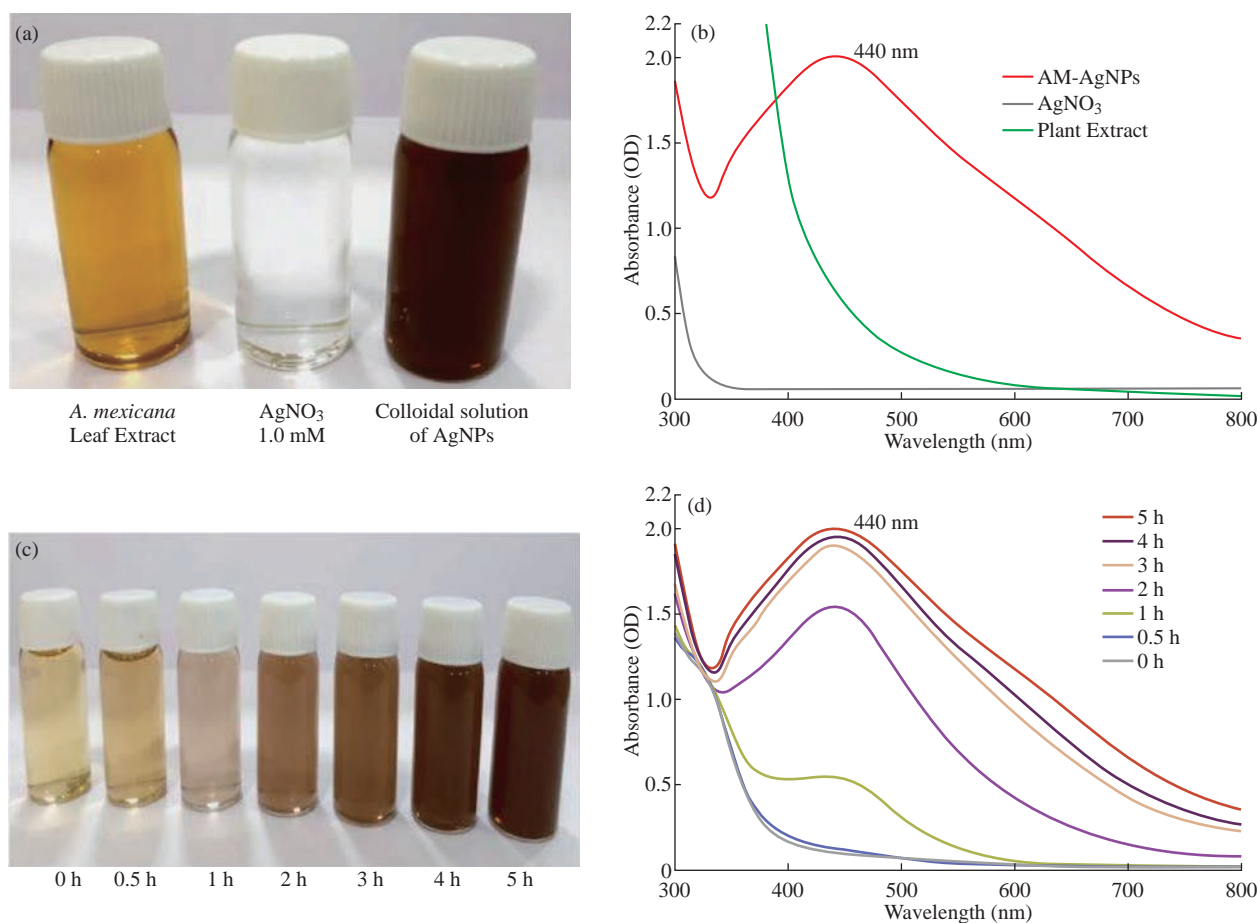

All statistical analyses were performed with SPSS for windows version 11.0 software. The IC<sub>50</sub> values with 95% confidence interval (50% cell growth inhibitory concentration) were reported as Mean  $\pm$  SEM of 3 independent experiments. Student's t-test was performed to examine the significant differences between means of AM-Ag NPs treated and control samples.

## Results and Discussion

This study helped to understand possible mechanism underlying the cytotoxicity and genotoxicity of biogenic silver nanoparticles synthesized using *A. mexicana* plant extract. This is the first report of its kind to provide evidence supporting AM-Ag NPs exhibited significant anti-proliferative and apoptotic potential against selected cancer cells, which suggested that biogenic AM-Ag NPs could be a new subsidiary therapeutic means for the treatment of variety of cancers.

### Biosynthesis and characterization of AM-Ag NPs

Biosynthesis of AM-Ag NPs using aqueous leaf extract of *A. mexicana* was demonstrated by change in colour of silver nitrate from colorless to brownish within 5 h of incubation at 80 °C (Fig. 1(a) and (c)). The change in color of AgNO<sub>3</sub> solution after incubation with *A. mexicana* leaf extract confirmed the formation of different sized silver nanoparticles which was triggered by secondary metabolites in phytochemicals present in *A. mexicana* responsible for bioreduction of silver ions to nanosilver. Further confirmation and characterization of biosynthesized AM-Ag NPs were done by UV-visible spectroscopy where the colloidal solution of AM-Ag NPs showed absorption peak at 440 nm (Fig. 1(b)). Furthermore, time dependent bioreduction of silver ions into AM-Ag NPs in colloidal solution was monitored at various time intervals of 30 min, 1 h, 2 h, 3 h, 4 h and 5 h respectively. The formation of AM-Ag NPs was started after 1 h of incubation and completed after 5 h (Fig. 1(d)).

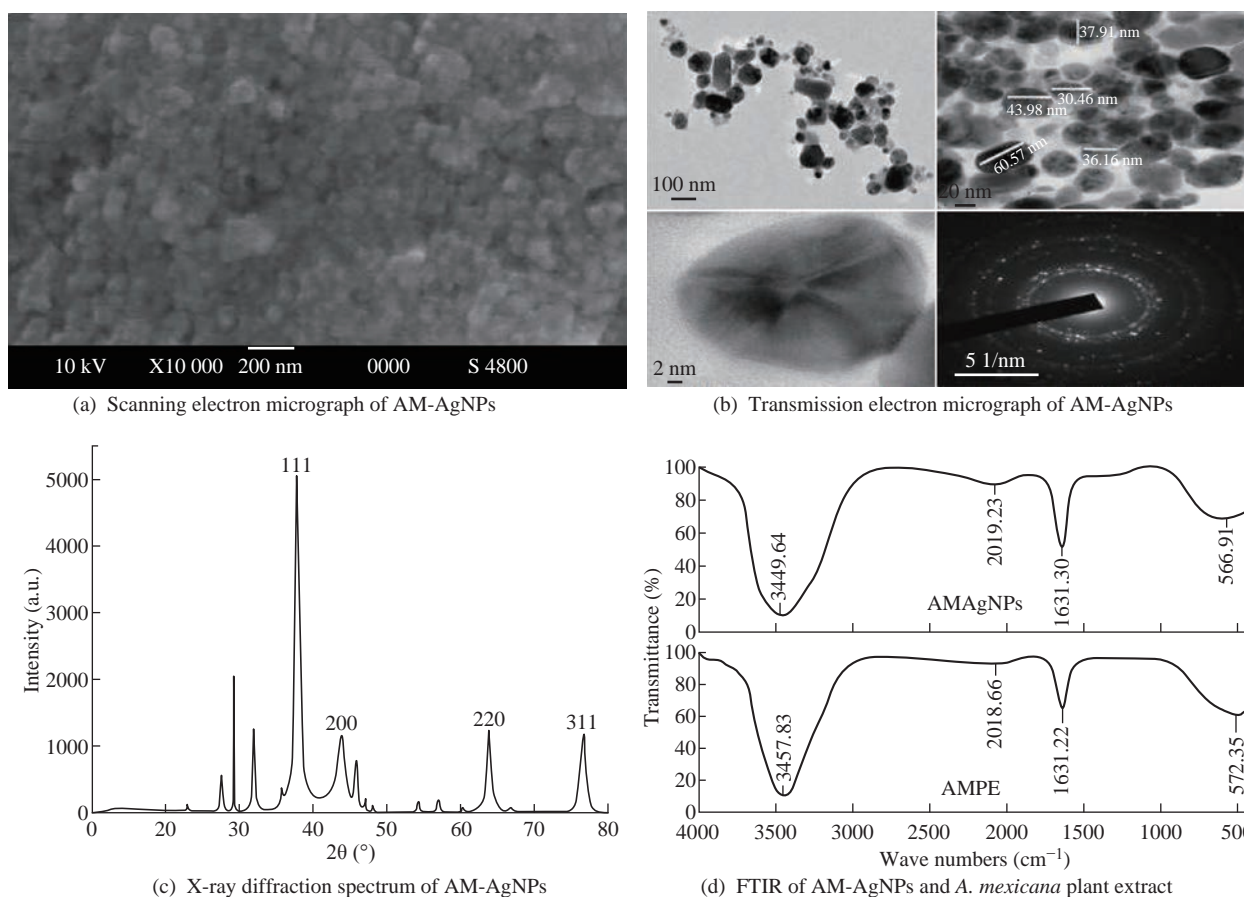

**Fig. 1** Biosynthesis of AM-Ag NPs, bottle containing (a) *A. mexicana* plant extract, sample of 1 mM  $\text{AgNO}_3$  and colloidal solution of AM-Ag NPs. (b) UV-visible spectra of *A. mexicana* plant extract,  $\text{AgNO}_3$  and AM-Ag NPs. The absorption spectrum exhibited a strong broad peak between 432 - 442 nm for Ag NPs. (c) Time dependent synthesis of biogenic AM-Ag NPs. Transformation of color of reaction mixture containing *A. mexicana* leaf extract and silver nitrate solution at various time periods (0 - 5 h). Time dependent UV-visible spectrometry analysis of formation of AM-Ag NPs at various time periods. The absorption spectrum exhibited a strong broad peak between 440 nm for Ag NPs.

The results of SEM revealed distribution of AM-Ag NPs (Fig. 2(a)). The morphology, size and shape of biosynthesized AM-Ag NPs were determined by TEM which showed the biosynthesized AM-Ag NPs were spherical in shape and 20 - 60 nm in size range (Fig. 2(b)). When we determined the size of AM-Ag NPs by dynamic light scattering (DLS), the results showed average size of AM-Ag NPs at 48.8 nm. (Supporting Information 1). XRD was used to confirm the crystalline nature of biosynthesized AM-Ag NPs where the pattern of important peaks at  $2\theta$  values of  $37.99^\circ$ ,  $44.15^\circ$ ,  $64.40^\circ$  and  $77.36^\circ$  corresponding to 111, 200, 220 and 311 planes of silver confirmed the crystalline nature of biogenic AM-Ag NPs (Fig. 2(c)). The FTIR peaks at 3449, 2019, 1631, 1383 and 566 confirmed O-H, C-H and C-N stretching of polyphenolic compounds during the formation of biogenic Ag NPs. Thus, the results of FTIR confirmed the role of phytochemicals present in *A. mexicana* in the process

of biogenic synthesis and stabilization of nanoparticles (Fig. 2(d)).

### Cytotoxicity of AM-Ag NPs

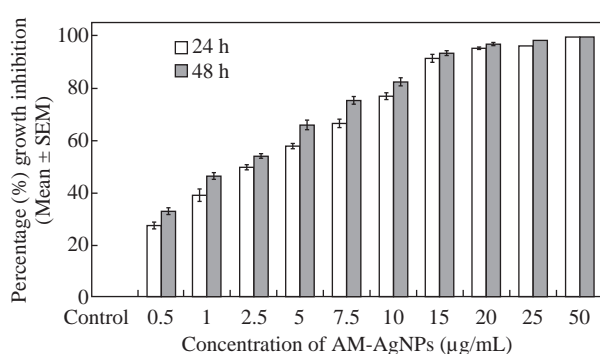

A number of studies revealed possible restorative prospective of biogenic silver nanoparticles on human cancer cell lines including human breast cancer cell line [20, 25] and lung cancer cell lines [26]. However, very limited information appeared in literature elucidating the mechanism involved in action of nanoparticles on cellular pathways during the inhibition of cell proliferation process. Therefore, in this study we demonstrated the evident mechanism of action of AM-Ag NPs on activation of apoptotic pathway in cancer cells. In the present study we found that AM-Ag NPs exerted growth inhibitory effects on studied breast and cervical cancer cell lines at concentration dependent manner where minimum concentration (20  $\mu\text{g/mL}$ ) inhibited more than 90%

**Fig. 2** Characterization of AM-Ag NPs: (a) SEM microscopic view of AM-Ag NPs; (b) TEM micrograph of AM-Ag NPs, scale bar = 20 nm and selected area electron diffraction (SAED) pattern at right corner; (c) XRD pattern of AM-Ag NPs synthesized using *A. mexicana* leaf extract; (d) FTIR spectrum of *A. mexicana* plant extract and AM-Ag NPs synthesized using aqueous extract of *A. mexicana* aqueous leaf extract.

cell growth after 48 h exposure. Comparatively, colon cancer cell line (HCT-15) required more than 50  $\mu\text{g/mL}$  of AM-Ag NPs to inhibit 90% cell growth. Only the report stating gold nanoparticles synthesized using *A. mexicana* inhibited cell growth of MCF-7 cells at 100  $\mu\text{g/mL}$  [27] which was found 5 times higher than what we reported for biogenic silver nanoparticles. The silver nanoparticles exerted most recognized noticeable effects on cultured cells with modifications in cellular morphology [14, 28]. When we treated cancer cells with higher concentrations of AM-Ag NPs, evident features of cellular apoptosis with alteration showed in cell morphology with shrunken appearance, cell contraction, extensive membrane bleb and loss of membrane integrity. In this study, the cytotoxic activity of biogenic AM-Ag NPs at concentrations between 0.5 - 50  $\mu\text{g/mL}$  were evaluated in vitro against cervical, breast and colon adenocarcinoma cell lines exposed to Ag NPs up to 48 h. When we exposed cancer cells to 0.5 - 50  $\mu\text{g/mL}$  AM-Ag NPs, we observed that 20  $\mu\text{g/mL}$  of Ag NPs inhibited  $95.34 \pm 0.23\%$  and  $97.17 \pm 0.40\%$

cell growth in HeLa cells after 24 and 48 h exposure respectively (Fig. 3(a)). Similarly, results of MCF-7 cells exposed to 20  $\mu\text{g/mL}$  of Ag NPs showed  $96.61 \pm 0.31\%$  and  $97.46 \pm 0.24\%$  cell growth inhibition after 24 and 48 h exposure (Fig. 3(c)). However, HCT-15 cells treated with increased concentrations of AM-Ag NPs, i.e., 50  $\mu\text{g/mL}$ , showed  $91.20 \pm 0.22\%$  and  $99.12 \pm 0.35\%$  cell growth inhibition after 24 and 48 h exposure respectively (Fig. 3(e)). 50% inhibitory concentration ( $\text{IC}_{50}$ ) of AM-Ag NPs required to inhibit cell growth of HeLa cells after 24 and 48 h exposure were  $2.80 \pm 0.73$ ; 95% CI: 1.34 - 4.21,  $p = 0.05$  and  $1.94 \pm 0.43$ ; 95% CI: 1.56 - 3.26,  $p = 0.05$  respectively.  $\text{IC}_{50}$  of AM-Ag NPs for inhibition of MCF-7 were  $3.50 \pm 0.40$ ; 95% CI: 2.85 - 4.46,  $p = 0.05$  after 24 h exposure and  $1.86 \pm 0.36$ ; 95% CI: 1.63 - 3.07,  $p = 0.05$  after 48 h respectively, whereas  $\text{IC}_{50}$  of AM-Ag NPs required for inhibition of HCT-15 cell growth were  $9.63 \pm 1.10$ ; 95% CI: 7.46 - 11.80,  $p = 0.05$  after 24 h exposure, and  $4.16 \pm 0.59$ ; 95% CI: 3.53 - 6.87,  $p = 0.05$  after 48 h exposure. The complete inhibition

(d) Morphology of MCF-7 cells after 24 h exposure to AM-AgNPs

(f) Morphology of HCT-15 cells after 24 h exposure to AM-AgNPs

**Fig. 3** Representative histogram showing in vitro cytotoxicity of biogenic AM-Ag NPs on (a) HeLa cells, (c) MCF-7 cells, (e) HCT-15 cells after 24 and 48 h exposure to 0.5, 1, 2.5, 5, 7.5, 10, 15, 20, 25 and 50 µg/mL concentrations of biogenic AM-Ag NPs. The results represent the means of 3 independent experiments, error bars representing the standard error of the mean. Cell morphology of (b) HeLa cells and (d) MCF-7 cells after 24 h exposure of different concentrations of 2.5, 5, 10, 15, and 20 µg/mL, and (f) HCT-15 cells exposed to 2.5, 5, 10, 20 and 25 µg/mL of biogenic AM-Ag NPs for 24 h. All images were taken at 20 × magnification with Carl Zeiss phase contrast microscope.

of cell growth (~99 %) of HeLa and MCF-7 cells was observed at 25 µg/mL, whereas 50 µg/mL of AM-Ag NPs inhibited HCT-15 cell growth. Cell morphological features of treated cells observed under inverted phase contrast microscope revealed the changes in cell morphology, whereas control cells appeared normal (Fig. 3(b), (d) and (f)). It was clearly observed that cells treated at 10 µg/mL and above concentrations possessed systematic morphological alterations such as cell shrinkage, cytoplasmic condensation and loss of membrane integrity as a signature of cell apoptosis. When we tested the cytotoxic activity of *A. mexicana*

plant extract, we found the  $IC_{50}$  concentration of aqueous extract of *A. mexicana* required to inhibit cell growth after 24 h exposure was  $58.88 \pm 2.74$  µg/mL for HeLa cells,  $134.89 \pm 2.36$  µg/mL for MCF-7 cells, and  $60.25 \pm 2.60$  µg/mL for HCT-15 cells respectively (Supporting Information 2(a)). Also, the cytotoxicity results of chemically synthesized citrate-Ag NPs showed comparatively lower inhibition of cell growth where 200 µg/mL of citrate-Au NPs killed  $82.06 \pm 1.29\%$  of MCF-7 cells,  $87.84 \pm 1.20\%$  of HeLa cells and  $90.26 \pm 0.80\%$  of HCT-15 cells (Supporting Information 2(b)). This study demonstrated the cytotoxicity effect of AM-

Ag NPs on normal fibroblast cells; the results indicated comparatively lower sensitivity of normal fibroblast cells towards either biogenic AM-Ag NPs or citrate-Ag NPs. By exposing fibroblast cells to 0.5 - 50  $\mu\text{g}/\text{mL}$  AM-Ag NPs as well as citrate-Ag NPs, we observed that even higher concentration, i.e, 50  $\mu\text{g}/\text{mL}$ , inhibited less than  $23.32 \pm 1.2\%$  and  $12.17 \pm 0.26\%$  cell growth in fibroblast cells after 48 h exposure respectively (Supporting Information 3(a) and (b)).

### DNA fragmentation

DNA damage is considered as one of the distinctive features of apoptosis process or cell death. The results of cytotoxicity concurred with previous reports where silver nanoparticles showed inhibition of cell proliferation in cancer cells including human breast [29, 30], lung [31], colon [32] and ovarian cancer cells [33] through induction of cellular apoptosis. Biogenic silver nanoparticles are known to exhibit cellular apoptotic effects in various cancer cells in accordance with cytotoxicity by means of different mechanisms causing macromolecular damage including DNA fragmentation [29, 34]. Previous studies reported DNA fragmentation induced cellular apoptosis in different cancer cells when exposed to silver nanoparticles [32], resembling to which our results proved induction DNA fragmentation in HeLa, MCF-7 and HCT-15 cells in response to exposure of biogenic AM-Ag NPs. The DNA isolated from HeLa and MCF-7 cells exposed to 5 - 20  $\mu\text{g}/\text{mL}$  and HCT-15 cells exposed

to 10 - 50  $\mu\text{g}/\text{mL}$  of AM-Ag NPs showed laddering appearance in fragmented DNA, indicating deposition of Ag NPs inside the cell nucleus and inducing dose dependent DNA damage. The results of evaluation of genotoxicity effects of AM-Ag NPs was determined by DNA fragmentation pattern in cancer cells. When HeLa and MCF-7 cells were treated with 0 - 20  $\mu\text{g}/\text{mL}$  (Fig. 4(a) and (b)) and HCT-15 cells were treated with 0 - 50  $\mu\text{g}/\text{mL}$  of AM-Ag NPs, the apoptotic cells showed characteristic DNA laddering from lower to higher concentrations (Fig. 4(c)). The cells treated with AM-Ag NPs exhibited extensive double strand breaks yielding a ladder appearance in DNA (Lane 4-7, Fig. 4(a)-(c)), while DNA of unexposed control cells exhibited minimum or no DNA breakage. Thus, extensive DNA double strand breaks observed in AM-Ag NPs treated cells evidenced the induction of apoptosis in HeLa, MCF-7 and HCT-15 cells.

### Effect AM-AgNPs on apoptotic gene and protein expression analysis

Inhibition of cell proliferation and induction of apoptosis are thought to be the major biological outputs of p53 mediated pathway in response to various types of physiological stressors. In view of this, when we exposed HeLa, MCF-7 and HCT-15 cells with  $\text{IC}_{50}$  concentration of AM-Ag NPs up to 48 h and evaluated the expression of caspase-3 and p53 genes at mRNA level and protein level, we observed significantly up-regulated expression of both caspase-3 and p53 in Ag

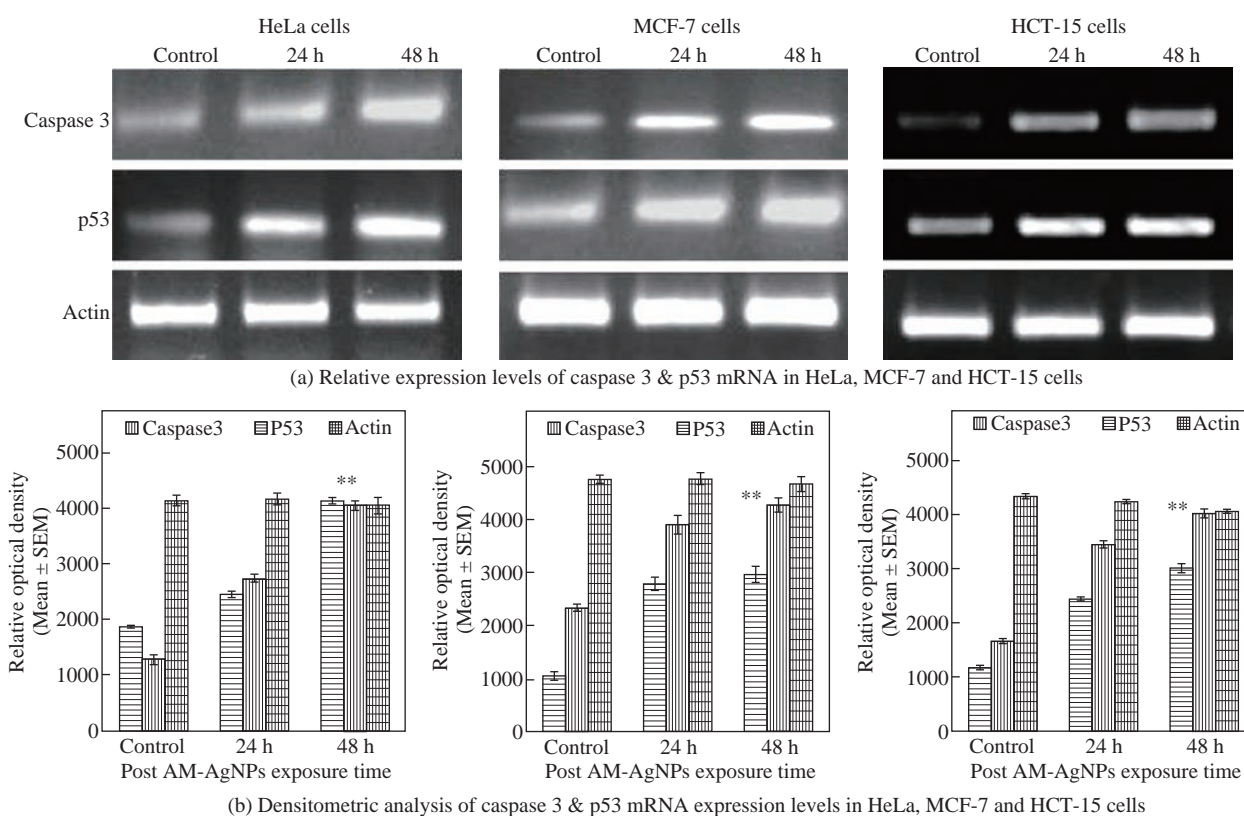

**Fig. 4** Genotoxicity of AM-Ag NPs against HeLa, MCF-7 and HCT-15 cells. Representative Agarose gel images showing DNA fragmentation in (a) HeLa, (b) MCF-7 and (c) HCT-15 cells treated with different concentrations of AM-Ag NPs. In each representative gel, lane 1 was 100 bp DNA marker: Lane 2 was DNA from control cells; lane 3-7 were DNA from AM-Ag NPs treated HeLa and MCF-7 cells (2.5, 5, 10, 15 and 20  $\mu\text{g}/\text{mL}$  respectively); lane 8 was 1 Kb DNA marker. HCT-15 cells were exposed to 5, 10, 20, 25 and 50  $\mu\text{g}/\text{mL}$  AM-Ag NPs.

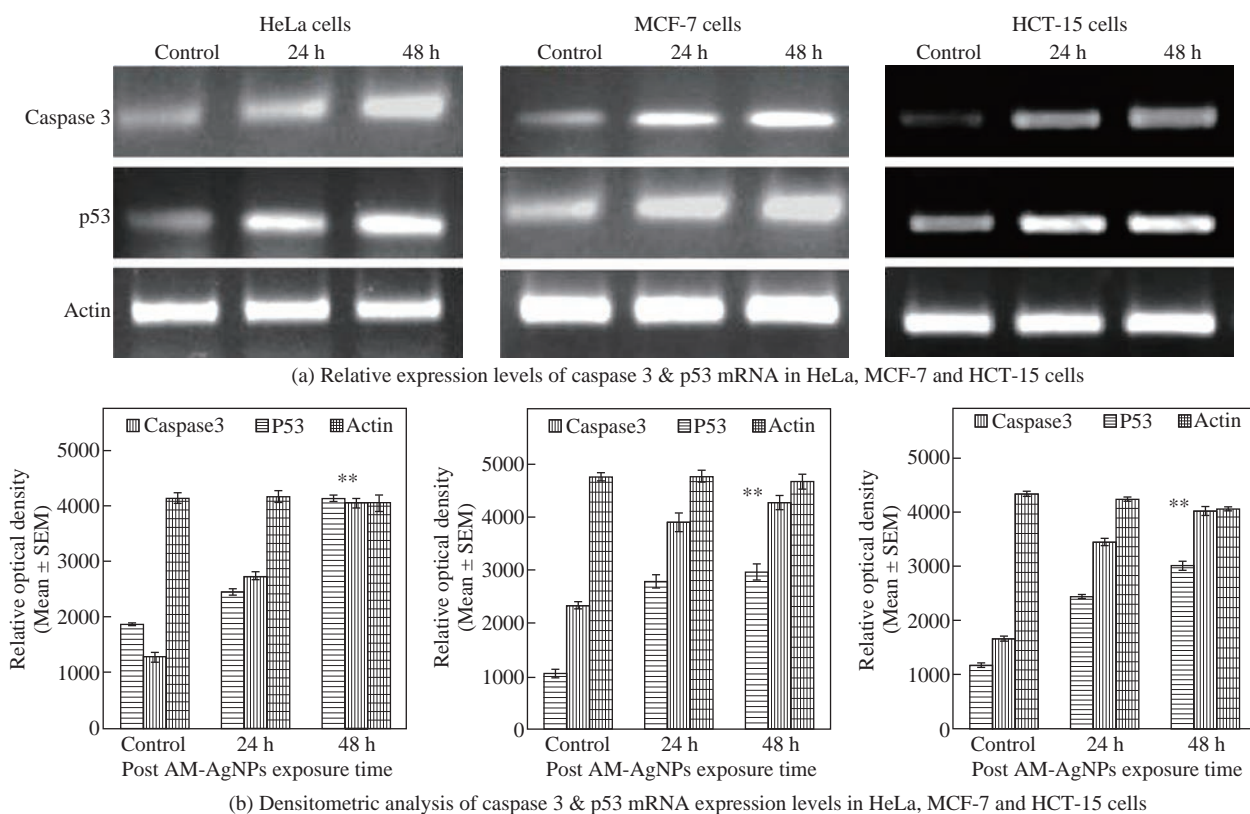

NPs treated cancer cells in time dependent manner as compared to control cells. The enhanced expression of both caspase-3 and p53 performed a primitive role in activation of apoptosis process. It was evident from our finding that the underlying mechanism of cell death in cancer cells by AM-Ag NPs was intrinsic apoptosis pathway mediated by activation of caspase-3 and p53. These results concurred with the earlier reports stating the regulation of biogenic Ag NPs mediated apoptosis in human breast cancer cells [33] and colon carcinoma cells [32] through involvement of p53 and activation of caspase-3. In this study, the expression apoptotic genes in AM-Ag NPs exposed cancer cells were analyzed using semi-quantitative RT-PCR and western blotting by exposing the cells with  $IC_{50}$  concentration of AM-Ag NPs till 48 h. When we aimed at checking the expression level of caspase-3 and p53 genes, it displayed an evidential enhanced expression of both genes excitingly up-regulated in AM-Ag NPs treated cancer cells as compared to control unexposed cells (Fig. 5(a)). The results represented remarked 2 - 3 fold

increased expression of studied caspase-3 and p53 in AM-Ag NPs treated cells as compared to respective controls after 24 and 48 h exposure. Thus, AM-Ag NPs significantly regulated the overexpression of both caspase-3 and p53 genes in all 3 type cells treated with nanoparticles up to 48 h ( $p < 0.001$ ) as compared to normal control cells (Fig. 5(b)).

Similarly, apoptotic protein expression analysis was performed to detect apoptotic proteins caspase-3 and p53 using western blot analysis in selected cancer cells exposed to  $IC_{50}$  concentration of AM-Ag NPs for 48 h. Our results depicted that the expression levels of caspase-3 and p53 proteins were also increased in cancer cells after exposure to AM-Ag NPs. These results signified up-regulation of caspase-3 and p53 proteins to execute the process of apoptosis in AM-Ag NPs exposed cancer cells as compared to untreated control cells (Fig. 6(a)). The expression of caspase-3 and p53 was observed significantly higher ( $p < 0.001$ ) in HeLa, MCF-7 and HCT-15 cells when exposed to AM-Ag NPs till 48h as compared to untreated

**Fig. 5 (a)** Representative RT-PCR products of caspase-3, p53 and actin genes from HeLa, MCF-7 and HCT-15 cells exposed to  $IC_{50}$  concentration of AM-Ag NPs with different time points of exposure. Lane 1 was mRNA level of caspase-3 and p53 from control cells; lane 2 and 3 were mRNA levels of AM-Ag NPs exposed cell samples after 24 and 48 h of exposure. **(b)** Histogram showing relative levels of caspase-3 and p53 cDNA of HeLa, MCF-7 and HCT-15 cells quantified by densitometry analysis, error bars indicating the standard error of the mean (SEM) for 3 independent experiments ( $n = 3$ ). Significant differences (\*\*) in mRNA expression between control and AM-Ag NPs exposed samples were assessed by Student's t-test ( $p < 0.001$ ), results found to be increased significantly in samples obtained from 24 and 48 h post exposure periods as compared to control.

**Fig. 6** (a) Representative western blot showing expression of caspase-3 and p53 protein from HeLa, MCF-7 and HCT-15 cells exposed to  $IC_{50}$  concentration of AM-Ag NPs with different time points ( $n = 3$ ). Lane 1 was levels of expression of caspase-3 and p53 from control cells; lane 2 and 3 were expressions of proteins from AM-Ag NPs exposed cells at 24 and 48 h exposure time. Actin was used as internal loading control to compare the expression levels. (b) Histogram showing relative levels of caspase-3 and p53 proteins resolved in western blot were quantitated by densitometric analysis. Error bars indicated the standard error of the mean (SEM) for 3 independent experiments ( $n = 3$ ). Significant differences (\*\*) were assessed by Student's t test ( $p < 0.001$ ), results found to be increased significantly in samples obtained from 24 and 48 h post exposure periods as compared to control.

control cells (Fig. 6(b)). When compared with control cells, 3 fold increased expression of caspase-3 and p53 occurred in AM-Ag NPs treated cells after 48 h exposure. We used actin as an internal loading control in both mRNA and protein expression studies and it did not change expression level when compared with other studied elements. Hence, our findings perceptibly indicated the underlying means and mode of inhibition of cell proliferation in cancer cells by AM-Ag NPs was a direct result of activation of intrinsic apoptosis pathway mediated via caspase-3 and p53 dependent manner.

## Conclusions

Around 95% inhibition of cell proliferation in HeLa and MCF-7 cells was recorded with 25  $\mu\text{g}/\text{mL}$  concentration of AM-Ag NPs, whereas 50  $\mu\text{g}/\text{mL}$  of AM-Ag NPs was required to kill 95% of HCT-15 cells. The findings from the current research evidenced involvement of molecular events such as activation

of caspase-3 and p53 which were intermediates of apoptotic cell death induced by biogenic AM-Ag NPs. Hence, our study provided plausible evidence supporting that AM-Ag NPs exhibited strong anti-proliferative and apoptotic potential against selected cancer cells, suggesting that biogenic AM-Ag NPs could act as a new substitute and help in therapeutics of cervix, breast and colon cancers.
